Installer barriers lead in each source; a turnaround improvement cannot be shown

The two partner summaries cannot be pooled, so there is no overall ranking of barriers. Within each source, the installer barrier is the most-cited one recorded.

Partner North: homeowner survey

40 homeowners · several barriers could be selected · bars show % of 40 homeowners

Selections overlap: the three counts sum to 54, so they are not shares of one total.

Partner South: open support cases

15 open cases reviewed · homeowners served not reported · bar shows % of 15 cases

Only this barrier is recorded. The review did not record whether other barriers were present, so no ranking is possible.

Did service turnaround improve?

- **South, recent period:** median 8 days from 11 of 15 cases (4 had no time recorded). Partial, not a full-period measure.
- **North:** no turnaround times reported.
- **Baseline:** "around two weeks last spring" has no case count, sample or method, so it is not comparable.

Answer: cannot be determined; no improvement is claimed.

Needed to answer both parts

1. One period definition and shared denominator for both partners.
2. South barrier counts recording every barrier per case or homeowner, with the denominator.
3. Turnaround for a baseline and the recent period, measured the same way, with case and missing-time counts.
4. Turnaround times from Partner North.

Fictional scenario; all figures are invented for the evaluation.
