The pilot supports deciding whether to run another measurement cycle, not wider installation

What the pilot measured

- A cooperative tested supplemental lighting on 18 greenhouse plots at three sites over one winter growing cycle.
- Each plot's yield difference is measured against its own site's reference plots.
- Plots were not randomly assigned. Crop mix and baseline conditions differed between sites.

Yield difference vs site reference plots (%), 18 plots. Shows the reported median and range only; individual plot values were not reported. Scale –5% to +15%.

12 of 18 plots had a positive difference; 6 did not.

The evidence supports

- Deciding whether to authorize another measurement cycle. The steering group can make that decision.
- Reporting the median yield difference (+6%) as a pilot result, with its –3% to +14% range.

The evidence does not support

- Wider installation on yield alone. Installation cost and energy use were not measured.
- Saying lighting caused the yield differences. Plots were not randomly assigned, and sites differed.
- Expecting a gain on every plot. 6 of 18 plots did not have a positive difference.

> **Open decision for the steering group:** whether to authorize another measurement cycle. Wider installation has not been approved.

Source: case brief. Fictional scenario; all figures are invented for this evaluation.
