RECENT INTAKE PERIOD · TWO PARTNER SUMMARIES · FICTIONAL SCENARIO

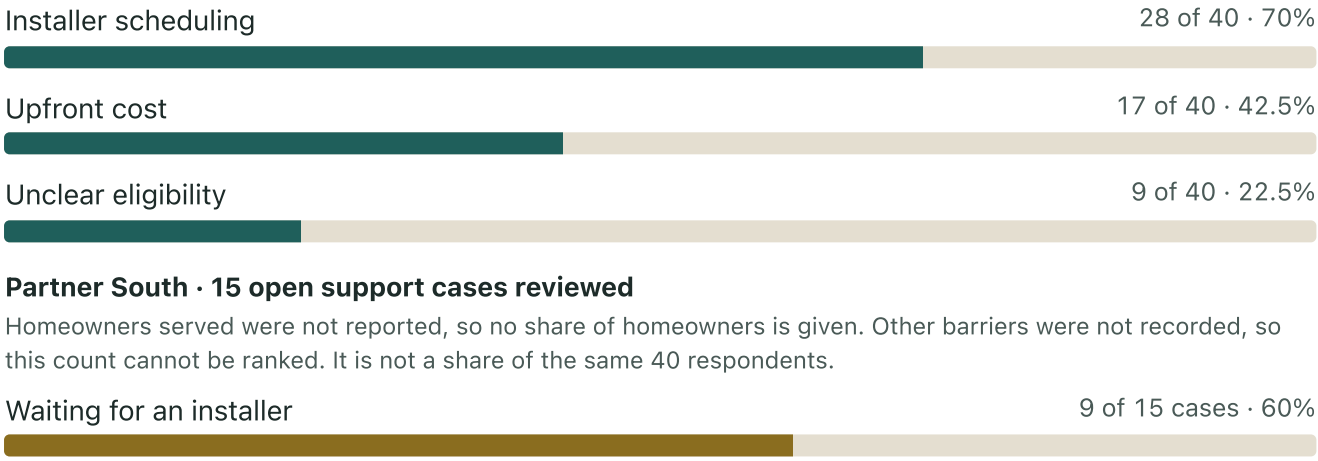

Installer scheduling leads Partner North's survey; an overall ranking and a turnaround change cannot be shown

Which barrier is most common?

> **Not established overall.** Within Partner North's survey, installer scheduling is the most-selected barrier: 28 of 40 respondents (70%). Partner South's 9 of 15 cases that mention waiting for an installer cannot be ranked against other barriers, because the review did not record them.

Partner North · survey of 40 homeowners

Respondents could select more than one barrier, so each share is of 40 respondents and the shares add to more than 100%.

Partner South · 15 open support cases reviewed

Homeowners served were not reported, so no share of homeowners is given. Other barriers were not recorded, so this count cannot be ranked. It is not a share of the same 40 respondents.

Did service turnaround improve?

> **Cannot tell.** There is no comparable baseline. The only turnaround median (Partner South, 8 days) is a recent, partial figure, and the "around two weeks last spring" note gives no cases, sample size, or method. No improvement is claimed.

> **Partner South, recent:** median 8 days, from 11 of 15 cases with a recorded time. 4 cases had no time recorded.

> **Partner South, free-text note:** "around two weeks last spring". The cases, sample size, and method are not identified, so this is not comparable with the median.

> **Partner North:** no service-turnaround times were included.

Needed to answer the question

- **Overall barrier ranking:** one barrier question for both partners; a rule for overlapping selections; a common denominator per source (homeowners served, respondents, or cases); full barrier coding for South's cases; and a documented mapping between the partners' categories. "Installer scheduling" and "waiting for an installer" are not assumed to be the same thing.
- **Turnaround change:** a defined start and end point; the same measure and period definition for a baseline period and the recent period, from both partners; case-level dates, or the cases and method behind the "last spring" estimate; and counts of cases with and without a recorded time in each period.

Fictional scenario; all figures are invented for this evaluation. The partners used separate reporting forms, with no shared period definition, denominator, or baseline measure, so their counts are not pooled.
