Installer scheduling leads North's survey; the sources cannot yet show whether turnaround improved

Partner North · survey of 40 homeowners · several barriers allowed per person

Most common barrier overall?

Cannot be determin

The sources use different units (40 respondents vs 15 cases), different counting rules, and no shared denominator. Within North alone, installer scheduling is highest (28 of 40).

Partner South · 15 open support cases · homeowner total not reported

9 of 15 cases

(60%) mention “waiting for an installer”.

Did service turnaround improve?

Cannot be shown: no comparable baseline.

South's recent, partial median is 8 days (11 of 15 cases; 4 without a time). North reported no turnaround times. The “around two weeks last spring” note has no cases, sample, or method.

Needed to answer: (1) one shared intake period and denominator for both partners; (2) per-homeowner barrier data, either single-select or coded with a rule for overlapping selections; (3) turnaround times for the same period from both partners, with the number of cases and the missing-time count; (4) a dated baseline with its sample and method, and the reason four South cases lack a time.

Fictional scenario; all figures are invented for the evaluation. Partners used separate reporting forms.
